

ABSTRACT OF THE DISCLOSURE

There is provided a method which can check whether or not internal data for operational risk evaluation of a business organization is collected from all computers in the business organization. In application execution servers, one or more agent for collecting loss events occurring in the computers is arranged. One or more network monitoring server connected to a network of the business organization is arranged. The network monitoring server monitors the network. When the application execution servers include a computer having no agent, the network monitoring server adds the presence of the computer having no agent to a monitoring log to make it possible to check whether the agents for collecting internal data is arranged in all computers for executing an application in the business organization. Therefore, an operational risk can be faithfully evaluated.
